

Things I did for this paper that were not necessary for my thesis

Before the formation of the GPC

- Track merging correction for Au+Au 200 – this proved to be much trickier for this data set than the others because of the size of the effect so needed additional work, above what was needed for the Cu+Cu and 62 GeV data. In addition, the event mixing for Au+Au 200 took a considerable amount of time and while Jana ran jobs for this, I managed the jobs.
- Redo the Au+Au and d+Au 200 analysis – Jana no longer had good records of the d+Au analysis and we needed to document it for the analysis note. Also, it was easier to redo the complete analysis with my code than to get Jana's output to work with the track merging correction output from my code and we needed to use the d-eta projection method for the yields.
- Decide which cuts in pT and centrality to use for Au+Au 200 and d+Au 200 – the d-phi method can sometimes compensate for poor statistics, can include some of the ridge, and does not reveal residual track merging effects as well. Therefore, the binning needed to be reconsidered for each plot.
- Redoing everything when we changed the dphi or deta cut or when someone asked for a minor modification – by the end I had scripts which did everything but I wrote and managed the scripts.
- Consistency checks with Oana and Joern's analysis
- Paper draft – of course I did much of the writing and editing but I also made & managed the cvs repository so Jana and I could both work on the paper
- Added a figure with the widths in dphi and deta
- Argued with Fuqiang for several weeks that Marco's code for the v2 parameterization, which we used, was consistent with... Marco's analysis
- Wrote most of the analysis note (including most of the changes from my thesis)

After the GPC formation

- Managed most paper comments
- Managed the paper web page
- Created the new figure, with some help from Jana for the style
- Modified the analysis note to include details on the new figure
- Responded to the vast majority of Fuqiang's demands
 - Multiple comparisons with Pawan – this was easier because of the flexibility of my code. I showed multiple times that my analysis was consistent with Pawan's analysis, never to convince Fuqiang even while the rest of the GPC was convinced.
 - Added many details to the analysis note on the 2D fits
 - Did multiple iterations on studies of the vertex z dependence of the correlations. This did not have to take as many iterations as it did but Fuqiang refused to articulate what he wanted and made his demands iteratively instead of spelling out the goal from the beginning.
